Maxima & minima for Functions of n-Variables

Definitions

- If $f: U \subset \mathbb{R}^n \rightarrow \mathbb{R}$ then $x_0 \in U$ is called a local ^(maximum) minimum if there is a neighborhood of x_0 where $f(x) \leq f(x_0)$
- A local min or max is called a local extremum
- A critical point is a point x_0 where either f is not differentiable at x_0 or $(Df)(x_0) = 0$. A critical pt that is not an extremum is called a saddle point.

Theorem: If $f: U \subset \mathbb{R}^n \rightarrow \mathbb{R}$ is

differentiable & $x_0 \in U$ is a local

extremum, then $(Df)(x_0) = 0$

(i.e., x_0 is a critical point of f)

Proof: Suppose x_0 is a ^{local} maximum
(or min)

then for any direction \vec{h} , $g(t) = f(\vec{x}_0 + t\vec{h})$

has a ^{local} ^{max} at $t=0$, $\Rightarrow g'(0) = 0$

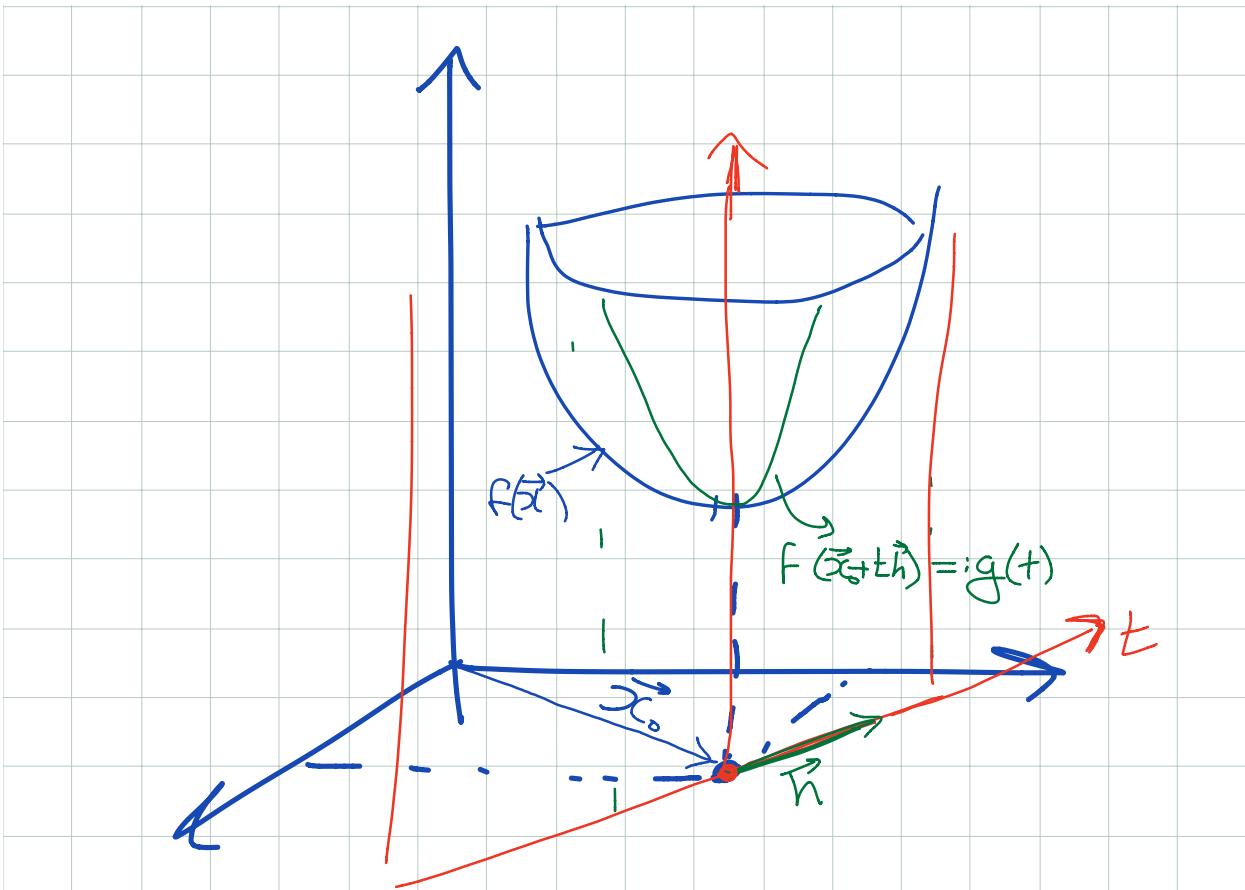

$$\text{but } g'(t) = (Df)|_{\vec{x}_0 + t\vec{h}} \vec{h}$$

$$\Rightarrow g'(0) = (Df)(\vec{x}_0) \cdot \vec{h} = 0$$

but this is true in every direction

$$\Rightarrow (Df)(x_0) = 0$$

Remark: This just means that $(\nabla f)|_{x_0} = 0$ or equivalently, that all the partial derivatives are zero.

Example: Find the critical points of the function $f(x, y) = x^2 + 4y^2$

Sol'n: The function is differentiable so we need to find the points where $\frac{\partial f}{\partial x} = \frac{\partial f}{\partial y} = 0$

$$\text{but } \frac{\partial f}{\partial x} = 2x \text{ & } \frac{\partial f}{\partial y} = 8y$$

so the point $(0,0)$ is the only critical pt.

— X —

Question

OK, so we now know how to find the critical points, but how to determine if they are a max, min, or saddle point?

Answer

For general functions $f: \mathbb{R}^n \rightarrow \mathbb{R}$
this can be fairly involved (see book)

However, we will deal with functions
of two variables

Second derivative test for functions of two variables

Let $f(x,y)$ be a C^2 function on an open set $U \subset \mathbb{R}^2$ (so $f: U \subset \mathbb{R}^2 \rightarrow \mathbb{R}$)

Suppose that

$$(i) \frac{\partial f}{\partial x}(x_0, y_0) = \frac{\partial f}{\partial y}(x_0, y_0) = 0$$

$$(ii) \frac{\partial^2 f}{\partial x^2}(x_0, y_0) > 0 \quad (<)$$

$$(iii) D = \left(\frac{\partial^2 f}{\partial x^2} \right) \left(\frac{\partial^2 f}{\partial y^2} \right) - \left(\frac{\partial^2 f}{\partial x \partial y} \right)^2 > 0$$

discriminant

at (x_0, y_0)

then (x_0, y_0) is a local minimum
(maximum)

If $D < 0$ at (x_0, y_0) then

(x_0, y_0) is a saddle point.

If $D = 0$, the test fails

Examples

- Find the critical points of the function $f(x,y) = x^2 + y^4$ and classify them (using the 2nd der. test)

• Sol'n: $\frac{\partial f}{\partial x} = 2x, \frac{\partial f}{\partial y} = 4y^3$

setting $\frac{\partial f}{\partial x} = 0 \Rightarrow x_0 = 0$

$\frac{\partial f}{\partial y} = 0 \Rightarrow y_0 = 0$

So our only critical point is $(0,0)$

Now, we must calculate

$$D = \left(\frac{\partial^2 f}{\partial x^2} \right) \left(\frac{\partial^2 f}{\partial y^2} \right) - \left(\frac{\partial^2 f}{\partial x \partial y} \right)^2$$

so we need $\frac{\partial^2 f}{\partial x^2} = 2, \frac{\partial^2 f}{\partial y^2} = 12y^2$

$$\left(\frac{\partial^2 f}{\partial x \partial y}\right)^2 = 0 \Rightarrow D(0,0) = 24y^2 \Big|_{(0,0)} = 0$$

so the test fails.

On the other hand, graphing

$f(x,y)$ shows that $(0,0)$ is a min.

Example : Same question for.

$$f(x,y) = \log(x^2 + y^2 + 1)$$

Sol'n :- $\frac{\partial f}{\partial x} = \frac{2x}{x^2 + y^2 + 1}$

$$\frac{\partial f}{\partial y} = \frac{2y}{x^2 + y^2 + 1}$$

\Rightarrow the critical point is $(0,0)$

Now, we have to calculate D :

$$\frac{\partial^2 f}{\partial x^2} \Big|_{(0,0)} = \frac{2(x^2 + y^2 + 1) - 2x(2x)}{(x^2 + y^2 + 1)^2} \Big|_{(0,0)} = 2$$

$$\text{Similarly } \frac{\partial^2 f}{\partial y^2} \Big|_{(0,0)} = 2$$

$$\frac{\partial^2 f}{\partial x \partial y} \Big|_{(0,0)} = \frac{-4xy}{(x^2+y^2+1)^2} \Big|_{(0,0)} = 0$$

$$\Rightarrow D(0,0) = (2)(2) - 0^2 = 4 > 0$$

$\Rightarrow (0,0)$ is a max or min

Now, we check $\frac{\partial^2 f}{\partial x^2}(0,0) > 0$

$\Rightarrow (0,0)$ is a local minimum.

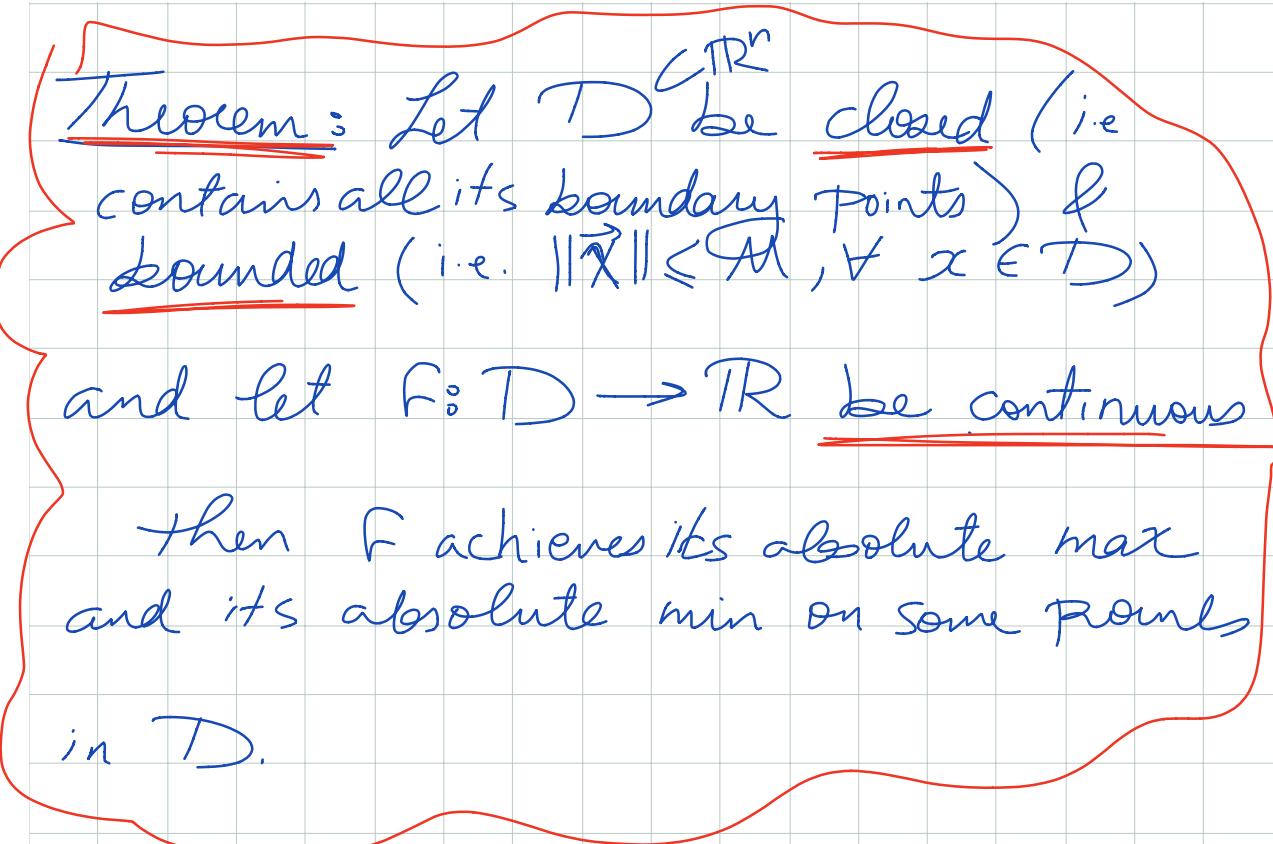

Global Maxima & Minima

Suppose $f: A \subset \mathbb{R}^2 \rightarrow \mathbb{R}$, A point

$x_0 \in A$ is an absolute max (or min)

if $f(x_0) \geq f(x)$ (or $\leq f(x)$)

for all $x \in A$

Theorem: Let $D \subset \mathbb{R}^n$ be closed (i.e. contains all its boundary points) & bounded (i.e. $\|\vec{x}\| \leq M, \forall x \in D$)
 and let $f: D \rightarrow \mathbb{R}$ be continuous
 then f achieves its absolute max and its absolute min on some points in D .

Strategy for finding Absolute maxima and minima on a region with a boundary

- (i) Locate all the critical points in the region.
- (ii) Find all the critical points of f viewed as a function on the boundary.
- (iii) Evaluate f at all the critical pts and select the largest & smallest

Example: Find the max and min values of

$$f(x, y) = x^2 + y^2 - x - y + 1$$

in the disk D defined by $x^2 + y^2 \leq 1$

Sol'n:

Step 1: Find the critical points in the interior of D .

$$\frac{\partial f}{\partial x} = 2x - 1, \quad \frac{\partial f}{\partial y} = 2y - 1$$

$$\frac{\partial f}{\partial x} = 0 \text{ & } \frac{\partial f}{\partial y} = 0 \Rightarrow x = \frac{1}{2}, y = \frac{1}{2}$$

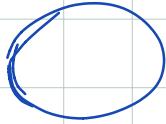

so $(\frac{1}{2}, \frac{1}{2})$ is the only critical pt. in the interior of the disk

(note that $(\frac{1}{2})^2 + (\frac{1}{2})^2 < 1$ so $(\frac{1}{2}, \frac{1}{2}) \in D$)

Step 2: Must find the critical pts on the boundary of D .

The boundary of D is the circle

$$x^2 + y^2 = 1$$

which can be parametrized as the set
of points $(\cos \theta, \sin \theta)$, $\theta \in [0, 2\pi]$

$$\text{So } f(x, y) = f(\cos \theta, \sin \theta)$$

$$\begin{aligned} &= \cos^2 \theta + \sin^2 \theta - \cos \theta - \sin \theta - 1 \\ &= -\cos \theta - \sin \theta \end{aligned}$$

To find the critical points on the circle
we need:

$$\frac{df}{d\theta} = -\sin \theta - \cos \theta$$

and set $\frac{df}{d\theta} = 0$ to get $\sin \theta = -\cos \theta$

$$\Rightarrow \theta = \frac{\pi}{4} \text{ or } \theta = \frac{5\pi}{4}$$

that is $(x, y) = (\cos \frac{\pi}{4}, \sin \frac{\pi}{4}) = (\frac{\sqrt{2}}{2}, \frac{\sqrt{2}}{2})$

& $(-\frac{\sqrt{2}}{2}, -\frac{\sqrt{2}}{2})$ are the CP's.

Step 3: $F\left(\frac{1}{2}, \frac{1}{2}\right) = \left(\frac{1}{2}\right)^2 + \left(\frac{1}{2}\right)^2 - \frac{1}{2} - \frac{1}{2} + 1 =$

$$= \frac{1}{2}$$

Similarly $F\left(\frac{\sqrt{2}}{2}, \frac{\sqrt{2}}{2}\right) = \frac{1}{2} + \frac{1}{2} - \frac{\sqrt{2}}{2} - \frac{\sqrt{2}}{2} + 1$

$$= 2 - \sqrt{2}$$

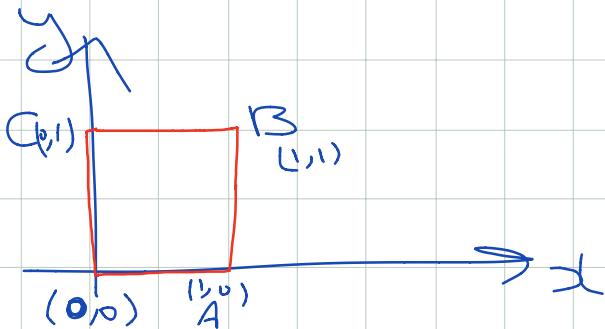

& $F\left(-\frac{\sqrt{2}}{2}, -\frac{\sqrt{2}}{2}\right) = 2 + \sqrt{2}$

$\Rightarrow \frac{1}{2}$ is the minimum
& $2 + \sqrt{2}$ is the maximum.

Example:

Determine the global extreme values of the function $f(x, y) = x^4 - y$
where $0 \leq x \leq 1, 0 \leq y \leq 1$

Solution

Step 1 : Find the critical pts.

$$\frac{\partial f}{\partial x} = 4x^3, \frac{\partial f}{\partial y} = -1$$

Since $\frac{\partial f}{\partial y} \neq 0$, there are no critical pts.

Step 2 : Check the boundary.

We have to check each edge of the square separately.

(i) Segment OA : Here $y=0, 0 \leq x \leq 1$

$$\Rightarrow f(x, 0) = x^4$$

$$\Rightarrow \begin{cases} \text{The max is } F(1, 0) = 1 \\ \text{The min is } F(0, 0) = 0 \end{cases}$$

(ii) Segment AB : Here $x=1, 0 \leq y \leq 1$

$$\Rightarrow f(1, y) = 1 - y$$

$$\Rightarrow \begin{cases} \text{The max is } F(1, 0) = 1 \\ \text{The min is } F(1, 1) = 0 \end{cases}$$

(ii) Segment BC : Here $y=1, 0 \leq x \leq 1$

$$\Rightarrow f(x, 1) = x^4 - 1$$

$$\Rightarrow \begin{cases} \text{the max is } f(1, 1) = 0 \\ \text{the min is } f(0, 1) = -1 \end{cases}$$

(iv) Segment CD : Here $x=0, 0 \leq y \leq 1$

$$\Rightarrow f(0, y) = 0 - y$$

$$\Rightarrow \begin{cases} \text{the max is } f(0, 0) = 0 \\ \text{the min is } f(0, 1) = -1 \end{cases}$$

So, the smallest value is $f_{\min} = -1$
and it is the global min on the square.

The largest value is $f_{\max} = 1$
and it is the global max on the square.
